

1. This was probably a wrong link. I tried the provided link but it just led me to the HiveMQ home page. I had to resort to AI to find a proper one.

2. An AI led me to this link and this is what I found. Exactly as it supposed to be. Took me long enough to figure out.

3. The Host from the instruction won't work so I resorted to the default. `Mqtt-dashboard.com` and port `8884`.

4. I published it! An DONE!

ANSWERS:

1. Did you notice a delay between clicking "Publish" and seeing the message in the "Subscriber" window? Why is low latency important for a warehouse fire sensor?
- **Yes I did noticed. Low latency is important because it ensures that critical real-time information can be acted upon before it becomes useless or dangerous. If a warehouse temperature sensor detects a fire or a chemical tank reaches a dangerous pressure limit, high latency means the automated cooling system or alarm won't trigger in time. Also will cause a late alarm to the staffs before evacuating the building.**
2. Did the "Device" need to know anything about the "Subscriber" (IP address, OS, etc.) to send the data? Explain how the **Broker** facilitates this "anonymity."
- **No, the "Device" (Publisher) did not need to know anything about the "Subscriber." It did not need its IP address, operating system, location, or even confirmation that the Subscriber was online.**
3. What happens to the "System" if the "Device" sends a message to the wrong topic (e.g., *warehouse/sensor/temp* instead of your specific name)?
- **If the Device sends a message to the wrong topic, the system or subscriber will receive absolutely nothinggg. Because the don't have the same topic path, it will lead nowhere unless the publisher's topic exists.**
